BOUNDARY CONDITIONS

Module to provide functions to add boundary conditions to each quantity on the centered grid that needs to be on the ghost grid for the upwind scheme.

`celestine.boundary_conditions.dissolved_gas_BCs(dissolved_gas_centers, cfg: Config)`

Add ghost cells with BCs to center quantity

`celestine.boundary_conditions.enthalpy_BCs(enthalpy_centers, cfg: Config)`

Add ghost cells with BCs to center quantity

`celestine.boundary_conditions.gas_BCs(gas_centers, cfg: Config)`

Add ghost cells with BCs to center quantity

`celestine.boundary_conditions.gas_fraction_BCs(gas_fraction_centers, cfg: Config)`

Add ghost cells with BCs to center quantity

`celestine.boundary_conditions.liquid_fraction_BCs(liquid_fraction_centers, cfg: Config)`

Add ghost cells to liquid fraction such that top and bottom boundaries take the same value as the top and bottom cell center

`celestine.boundary_conditions.liquid_salinity_BCs(liquid_salinity_centers, cfg: Config)`

Add ghost cells with BCs to center quantity

`celestine.boundary_conditions.pressure_BCs(pressure_centers, cfg: Config)`

Add ghost cells to pressure so that $W_l=0$ at $z=0$ and $p=0$ at $z=-1$

`celestine.boundary_conditions.salt_BCs(salt_centers, cfg: Config)`

Add ghost cells with BCs to center quantity

`celestine.boundary_conditions.temperature_BCs(temperature_centers, time, cfg: Config)`

Add ghost cells with BCs to center quantity

Note this needs the current time as well as top temperature is forced.

DIMENSIONAL PARAMS

Dimensional parameters required to run a simulation and convert output to dimensional variables.

The DimensionalParams class contains all the dimensional parameters needed to produce a simulation configuration.

The Scales class contains all the dimensional parameters required to convert simulation output between physical and non-dimensional variables.

```
class celestine dimensional_params.DimensionalParams(name: str, total_time_in_days: float = 365,  
                                                    savefreq_in_days: float = 1, data_path: str =  
                                                    'data/', lengthscale: float = 1, liquid_density:  
                                                    float = 1028, gas_density: float = 1,  
                                                    saturation_concentration: float = 1e-05,  
                                                    ocean_salinity: float = 34, eutectic_salinity:  
                                                    float = 270, eutectic_temperature: float = -  
                                                    21.1, latent_heat: float = 334000.0,  
                                                    specific_heat_capacity: float = 4184,  
                                                    thermal_conductivity: float = 0.598,  
                                                    salt_diffusivity: float = 0, gas_diffusivity: float = 0,  
                                                    frame_velocity_dimensional: float = 0,  
                                                    gravity: float = 9.81, liquid_viscosity: float =  
                                                    0.00089, bubble_radius: float = 0.001,  
                                                    pore_radius: float = 0.001,  
                                                    pore_throat_scaling: float = 0.5,  
                                                    drag_exponent: float = 6.0,  
                                                    liquid_velocity_dimensional: float = 0.0)
```

Contains all dimensional parameters needed to calculate non dimensional numbers.

To see the units each input should have look at the comment next to the default value.

property B

calculate the non dimensional rise velocity of the gas bubbles as

$$B = \frac{\rho_l g R_B^2 h}{3\mu\kappa}$$

property bubble_radius_scaled

calculate the bubble radius divided by the pore scale

$$\Lambda = R_B / R_0$$

property concentration_ratio

Calculate concentration ratio as

$$C = S_i / \Delta S$$

property expansion_coefficient

calculate

$$\chi = \rho_l \xi_{\text{sat}} / \rho_g$$

property frame_velocity

calculate the frame velocity in non dimensional units

```
get_config(boundary_conditions_config: BoundaryConditionsConfig =  
            BoundaryConditionsConfig(initial_conditions_choice='uniform', far_gas_sat=1.0,  
            far_temp=0.1, far_bulk_salinity=0), forcing_config: ForcingConfig =  
            ForcingConfig(temperature_forcing_choice='constant', constant_top_temperature=- 1.5,  
            offset=- 1.0, amplitude=0.75, period=4.0), numerical_params: NumericalParams =  
            NumericalParams(I=50, timestep=0.0002, regularisation=1e-06, solver='LU'))
```

Return a Config object for the simulation.

physical parameters and Darcy law parameters are calculated from the dimensional input. You can modify the numerical parameters and boundary conditions and forcing provided for the simulation.

get_darcy_law_params()

return a DarcyLawParams object

get_physical_params()

return a PhysicalParams object

get_scales()

return a Scales object used for converting between dimensional and non dimensional variables.

property lewis_gas

Calculate the lewis number for dissolved gas, return np.inf if there is no dissolved gas diffusion.

$$\text{Le}_\xi = \kappa / D_\xi$$

property lewis_salt

Calculate the lewis number for salt, return np.inf if there is no salt diffusion.

$$\text{Le}_S = \kappa / D_s$$

property liquid_velocity

convert given liquid velocity into non dimensional units

classmethod load(path)

load this object from a yaml configuration file.

property ocean_freezing_temperature

calculate salinity dependent freezing temperature using liquidus for typical ocean salinity

$$T_i = T_L(S_i) = T_E S_i / S_E$$

property salinity_difference

calculate difference between eutectic salinity and typical ocean salinity

$$\Delta S = S_E - S_i$$

save()

save this object to a yaml file in the specified data path.

The name will be the name given with _dimensional appended to distinguish it from a saved non-dimensional configuration.

property savefreq

calculate the save frequency in non dimensional time

property stefan_number

calculate Stefan number

$$St = L/c_p \Delta T$$

property temperature_difference

calculate

$$\Delta T = T_i - T_E$$

property thermal_diffusivity

Return thermal diffusivity in m2/s

$$\kappa = \frac{k}{\rho_l c_p}$$

property total_time

calculate the total time in non dimensional units for the simulation

class celestine.dimensional_params.Scales(*lengthscale: float, thermal_diffusivity: float, ocean_salinity: float, salinity_difference: float, ocean_freezing_temperature: float, temperature_difference: float, gas_density: float, saturation_concentration: float*)

convert_dimensional_bulk_air_to_argon_content(*dimensional_bulk_gas*)

Convert kg/m3 of air to micromole of Argon per Liter of ice

convert_from_dimensional_bulk_gas(*dimensional_bulk_gas*)

Non dimensionalise bulk gas content in kg/m3

convert_from_dimensional_bulk_salinity(*dimensional_bulk_salinity*)

Non dimensionalise bulk salinity in g/kg

convert_from_dimensional_dissolved_gas(*dimensional_dissolved_gas*)

convert from dissolved gas in kg(gas)/kg(liquid) to dimensionless

convert_from_dimensional_grid(*dimensional_grid*)

Non dimensionalise domain depths in meters

convert_from_dimensional_temperature(*dimensional_temperature*)

Non dimensionalise temperature in deg C

convert_from_dimensional_time(*dimensional_time*)

Non dimensionalise time in days

convert_to_dimensional_bulk_gas(*bulk_gas*)

Convert dimensionless bulk gas content to kg/m³

convert_to_dimensional_bulk_salinity(*bulk_salinity*)

Convert non dimensional bulk salinity to g/kg

convert_to_dimensional_dissolved_gas(*dissolved_gas*)

convert from non dimensional dissolved gas to dimensional dissolved gas in kg(gas)/kg(liquid)

convert_to_dimensional_grid(*grid*)

Get domain depths in meters from non dimensional values

convert_to_dimensional_temperature(*temperature*)

get temperature in deg C from non dimensional temperature

convert_to_dimensional_time(*time*)

Convert non dimensional time into time in days since start of simulation

celestine_dimensional_params.calculate_timescale_in_days(*lengthscale*, *thermal_diffusivity*)

calculate timescale given domain height and thermal diffusivity.

Parameters

- **lengthscale** (*float*) – domain height in m
- **thermal_diffusivity** (*float*) – thermal diffusivity in m²/s

Returns

timescale in days

celestine_dimensional_params.calculate_velocity_scale_in_m_day(*lengthscale*, *thermal_diffusivity*)

calculate the velocity scale given domain height and thermal diffusivity

Parameters

- **lengthscale** (*float*) – domain height in m
- **thermal_diffusivity** (*float*) – thermal diffusivity in m²/s

Returns

velocity scale in m/day

ENTHALPY METHOD

Module containing enthalpy method to calculate state variables from bulk enthalpy, bulk salinity and bulk gas.

class celestine.enthalpy_method.**EnthalpyMethod**(*physical_params*: [PhysicalParams](#))

Template for an enthalpy method. To implement a new method overwrite the initializer to initialise the physical parameters and a suitable phase boundaries object. Then implement a calculate enthalpy method that takes a state and uses bulk enthalpy, salt and gas to return (temperature, liquid_fraction, gas_fraction, solid_fraction, liquid_salinity, dissolved_gas).

class celestine.enthalpy_method.**FullEnthalpyMethod**(*physical_params*: [PhysicalParams](#))

class celestine.enthalpy_method.**ReducedEnthalpyMethod**(*physical_params*: [PhysicalParams](#))

celestine.enthalpy_method.**get_enthalpy_method**(*cfg*)

Return the enthalpy method object required depending on solver choice

LU: Full RED: Reduced SCI: Reduced

Parameters

cfg – configuration for simulation

Module for calculating the fluxes using upwind scheme

`celestine.flux.calculate_conductive_heat_flux(temperature, D_g)`

Calculate conductive heat flux as

$$-\frac{\partial \theta}{\partial z}$$

Parameters

- **temperature** (*Numpy Array of size I+2*) – temperature including ghost cells
- **D_g** (*Numpy Array*) – difference matrix for ghost grid

Returns

conductive heat flux

`celestine.flux.calculate_diffusive_salt_flux(liquid_salinity, liquid_fraction, D_g, cfg)`

Take liquid salinity and liquid fraction on ghost grid and interpolate liquid fraction geometrically

`celestine.flux.take_forward_euler_step(quantity, flux, timestep, D_e)`

Advance the given quantity one forward Euler step using the given flux

The quantity is given on cell centers and the flux on cell edges.

Discretise the conservation equation

$$\frac{\partial Q}{\partial t} = -\frac{\partial F}{\partial z}$$

as

$$Q^{n+1} = Q^n - \Delta t \left(\frac{\partial F}{\partial z} \right)$$

FORCING

Module for providing surface temperature forcing to simulation.

Note that the barrow temperature data is read in from a file if needed by the simulation configuration.

`celestine.forcing.barrow_temperature_forcing(time, cfg)`

Take non dimensional time and return non dimensional air temperature at the Barrow site in 2009.

For this to work you must have created the configuration `cfg` from dimensional parameters as it must have the conversion scales object.

`celestine.forcing.dimensional_barrow_temperature_forcing(time_in_days, cfg: Config)`

Take time in days and linearly interp 2009 Barrow air temperature data to get temperature in degrees Celsius.

GRIDS

Module providing functions to initialise the different grids and interpolate quantities between them.

`celestine.grids.add_ghost_cells(centers, bottom, top)`

Add specified bottom and top value to center grid

Parameters

- **centers** (*Numpy array*) – numpy array on centered grid (size I).
- **bottom** (*float*) – bottom value placed at index 0.
- **top** (*float*) – top value placed at index -1.

Returns

numpy array on ghost grid (size I+2).

`celestine.grids.average(ghosts)`

Returns arithmetic mean pairwise of first dimension of an array

This should get values on the ghost grid and returns the arithmetic average onto the edge grid

`celestine.grids.geometric(ghosts)`

Returns geometric mean of the first dimension of an array

INITIAL CONDITIONS

Module to provide initial state of bulk enthalpy, bulk salinity and bulk gas for the simulation.

`celestine.initial_conditions.apply_value_in_ice_layer(depth_of_ice, ice_value, liquid_value, grid)`

assume that top part of domain contains mushy ice of given depth and lower part of domain is liquid. This function returns output on the given grid where the ice part of the domain takes one value and the liquid a different.

This is useful for initialising the barrow simulation where we have an initial ice layer.

`celestine.initial_conditions.get_barrow_initial_conditions(cfg: Config)`

initialise domain with an initial ice layer of given temperature and bulk salinity. These values are hard coded in from Moreau paper to match barrow study. They also assume that the initial ice layer has 1/5 the saturation amount in pure liquid of dissolved gas to account for previous gas loss.

Initialise with bulk gas being (1/5) in ice and saturation in liquid. Bulk salinity is 5.92 g/kg in ice and ocean value in liquid. Enthalpy is calculated by inverting temperature relation in ice and ocean. Ice temperature is given as -8.15 degC and ocean is the far value from boundary config.

`celestine.initial_conditions.get_uniform_initial_conditions(cfg)`

Generate uniform initial solution on the ghost grid

Returns

initial solution arrays on ghost grid (enthalpy, salt, gas, pressure)

LOGGING CONFIG

Module to create logger for simulation

PARAMS

Classes containing parameters required to run a simulation

The config class contains all the parameters needed to run a simulation as well as methods to save and load this configuration to a yaml file.

```
class celestine.params.BoundaryConditionsConfig(initial_conditions_choice: str = 'uniform',
                                                far_gas_sat: float = 1.0, far_temp: float = 0.1,
                                                far_bulk_salinity: float = 0)
```

values for bottom (ocean) boundary

```
class celestine.params.Config(name: str, physical_params: PhysicalParams =
    PhysicalParams(expansion_coefficient=0.029, concentration_ratio=0.17,
    stefan_number=4.2, lewis_salt=inf, lewis_gas=inf, frame_velocity=0),
    boundary_conditions_config: BoundaryConditionsConfig =
    BoundaryConditionsConfig(initial_conditions_choice='uniform',
    far_gas_sat=1.0, far_temp=0.1, far_bulk_salinity=0), darcy_law_params:
    DarcyLawParams = DarcyLawParams(B=100, bubble_radius_scaled=1.0,
    pore_throat_scaling=0.5, drag_exponent=6.0, liquid_velocity=0.0),
    forcing_config: ForcingConfig =
    ForcingConfig(temperature_forcing_choice='constant',
    constant_top_temperature=- 1.5, offset=- 1.0, amplitude=0.75, period=4.0),
    numerical_params: NumericalParams = NumericalParams(I=50,
    timestep=0.0002, regularisation=1e-06, solver='LU'), scales: Optional[int]
    = None, total_time: float = 4.0, savefreq: float = 0.0005, data_path: str =
    'data/')
```

contains all information needed to run a simulation and save output

this config object can be saved and loaded to a yaml file.

```
check_thermal_Courant_number()
```

Check if courant number for thermal diffusion term is low enough for explicit method and if it isn't log a warning.

```
class celestine.params.DarcyLawParams(B: float = 100, bubble_radius_scaled: float = 1.0,
    pore_throat_scaling: float = 0.5, drag_exponent: float = 6.0,
    liquid_velocity: float = 0.0)
```

non dimensional parameters for calculating liquid and gas darcy velocities

```
class celestine.params.ForcingConfig(temperature_forcing_choice: str = 'constant',
    constant_top_temperature: float = - 1.5, offset: float = - 1.0,
    amplitude: float = 0.75, period: float = 4.0)
```

choice of top boundary (atmospheric) forcing and required parameters

load_forcing_data()

populate class attributes with barrow dimensional air temperature and time in days (with missing values filtered out).

Note the metadata explaining how to use the barrow temperature data is also in celestine/forcing_data. The indices corresponding to days and air temp are hard coded in as class variables.

```
class celestine.params.NumericalParams(I: int = 50, timestep: float = 0.0002, regularisation: float = 1e-06, solver: str = 'LU')
```

parameters needed for discretisation and choice of numerical method

property Courant

This number must be <0.5 for stability of temperature diffusion terms

```
class celestine.params.PhysicalParams(expansion_coefficient: float = 0.029, concentration_ratio: float = 0.17, stefan_number: float = 4.2, lewis_salt: float = inf, lewis_gas: float = inf, frame_velocity: float = 0)
```

non dimensional numbers for the mushy layer

```
celestine.params.filter_missing_values(air_temp, days)
```

Filter out missing values are recorded as 9999

PHASE BOUNDARIES

Module for calculating the phase boundaries needed for the enthalpy method.

class celestine.phase_boundaries.**FullPhaseBoundaries**(*physical_params*: PhysicalParams)

calculates the phase boundaries when we include gas fraction in bulk enthalpy and bulk salinity.

class celestine.phase_boundaries.**PhaseBoundaries**(*physical_params*: PhysicalParams)

Template for phase boundary calculation.

Concrete implementations should use the state containing enthalpy, salt and gas to calculate the liquidus, enthalpy, solidus and saturation boundaries and then return masks for each possible phase of the system.

class celestine.phase_boundaries.**ReducedPhaseBoundaries**(*physical_params*: PhysicalParams)

calculates the phase boundaries neglecting the gas fraction so that

$$\phi_s + \phi_l = 1$$

RUN SIMULATION

Module to run the simulation on the given configuration with the appropriate solver.

`celestine.run_simulation.run_batch(list_of_cfg)`

Run a batch of simulations from a list of configurations.

Each simulation name is logged, as well as if it successfully runs or crashes. Output from each simulation is saved in a .npz file.

Parameters

`list_of_cfg` (`List[celestine.params.Config]`) – list of configurations

`celestine.run_simulation.solve(cfg: Config)`

Solve simulation choosing appropriate solver from the choice in the config.

STATE

Classes to store solution variables

State: store variables on cell centers StateBCs: add boundary conditions in ghost cells to cell center variables Solution: store primary variables at each timestep we want to save data

```
class celestine.state.Solution(cfg: Config)
```

store solution at specified times on the center grid

```
    add_state(state: State, index: int)
```

add state to stored solution at given time index

```
class celestine.state.State(cfg: Config, time, enthalpy, salt, gas, pressure=None)
```

Stores information needed for solution at one timestep on cell centers

```
class celestine.state.StateBCs(state: State)
```

Stores information needed for solution at one timestep with BCs on ghost cells as well

Note must initialise once enthalpy method has already run on State.

VELOCITIES

Module to calculate Darcy velocities.

`celestine.velocities.calculate_absolute_permeability(liquid_fraction)`
calculate absolute permeability as

$$\Pi = \phi_l^3$$

`celestine.velocities.calculate_bubble_radius(liquid_fraction, cfg: Config)`

Takes liquid fraction on edges and returns bubble radius parameter on edges

`celestine.velocities.calculate_gas_interstitial_velocity(liquid_fraction, pressure, D_g, cfg: Config)`

Calculate V_g from liquid fraction and pressure on ghost grid

Return V_g on edge grid

`celestine.velocities.calculate_liquid_darcy_velocity(liquid_fraction, pressure, D_g)`

Calculate liquid Darcy velocity as

$$W_l = -\Pi(\phi_l) \frac{\partial p}{\partial z}$$

Parameters

- **liquid_fraction** (*Numpy Array (size I+2)*) – liquid fraction on ghost grid
- **pressure** (*Numpy Array (size I+2)*) – pressure on ghost grid
- **D_g** (*Numpy Array (size I+2)*) – difference matrix for ghost grid

Returns

liquid darcy velocity on edge grid

`celestine.velocities.calculate_velocities(state_BCs, D_g, cfg: Config)`

Inputs on ghost grid, outputs on edge grid

`celestine.velocities.solve_pressure_equation(state_BCs, new_state_BCs, timestep, D_e, D_g, cfg: Config)`

Calculate pressure on ghost grid from current and new state on ghost grid

Return new pressure on centers but easy to add boundary conditions

TEMPLATE

Template for a solver concrete solvers should inherit and overwrite required methods

```
class celestine.solvers.template.SolverTemplate(cfg: Config)
```

```
    generate_initial_solution()
```

Generate initial solution on the ghost grid

Returns

initial solution arrays on ghost grid (enthalpy, salt, gas, pressure)

```
    pre_solve_checks()
```

Optionally implement this method if you want to check anything before running the solver.

For example to check the timestep and grid step satisfy some constraint.

```
    abstract take_timestep(state: State) → State
```

advance enthalpy, salt, gas and pressure to the next timestep.

Note as of 2023-05-17 removed ability to have adaptive timestepping for simplicity.

Parameters

state (celestine.solvers.template.State) – object containing current time, enthalpy, salt, gas, pressure and surface temperature.

Returns

state of system (new enthalpy, salt, gas and pressure) after one timestep.

LAGGED SOLVER

class celestine.solvers.lagged_solver.LaggedUpwindSolver(*cfg*: [Config](#))

Take timestep using upwind scheme with liquid velocity calculation lagged.

pre_solve_checks()

Optionally implement this method if you want to check anything before running the solver.

For example to check the timestep and grid step satisfy some constraint.

take_timestep(*state*: [State](#))

advance enthalpy, salt, gas and pressure to the next timestep.

Note as of 2023-05-17 removed ability to have adaptive timestepping for simplicity.

Parameters

state (celestine.solvers.template.State) – object containing current time, enthalpy, salt, gas, pressure and surface temperature.

Returns

state of system (new enthalpy, salt, gas and pressure) after one timestep.

REDUCED MODEL SOLVER

class celestine.solvers.reduced_solver.ReducedSolver(*cfg*: Config)

Take timestep using forward Euler upwind scheme using reduced model.

pre_solve_checks()

Optionally implement this method if you want to check anything before running the solver.

For example to check the timestep and grid step satisfy some constraint.

take_timestep(*state*: State)

advance enthalpy, salt, gas and pressure to the next timestep.

Note as of 2023-05-17 removed ability to have adaptive timestepping for simplicity.

Parameters

state (celestine.solvers.template.State) – object containing current time, enthalpy, salt, gas, pressure and surface temperature.

Returns

state of system (new enthalpy, salt, gas and pressure) after one timestep.

celestine.solvers.reduced_solver.prevent_gas_rise_into_saturated_cell(*Vg*, *state_BCs*: StateBCs)

Modify the gas interstitial velocity to prevent bubble rise into a cell which is already theoretically saturated with gas.

From the state with boundary conditions calculate the gas and solid fraction in the cells (except at lower ghost cell). If any of these are such that there is more gas fraction than pore space available then set gas interstitial velocity to zero on the edge below. Make sure the very top boundary velocity is not changed as we want to always allow flux to the atmosphere regardless of the boundary conditions imposed.

Parameters

- **Vg** (Numpy array (size *I+1*)) – gas interstitial velocity on cell edges
- **state_BCs** (celestine.state.StateBCs) – state of system with boundary conditions

Returns

filtered gas interstitial velocities on edges to prevent gas rise into a fully gas saturated cell

SCIPY SOLVER

class `celestine.solvers.scipy.ScipySolver`(*cfg*: [Config](#))

Solve reduced model using scipy `solve_ivp` using RK23 solver. This is the “SCI” solver option.

Impose a maximum timestep constraint using courant number for thermal diffusion as this is an explicit method.

This solver uses adaptive timestepping which makes it a good choice for running simulations with large buoyancy driven gas bubble velocities and we save the output at intervals given by the `savefreq` parameter in configuration.

The interface of this class is a little different as we overwrite the solve method from the template and must provide a function to calculate the ode forcing for `solve_ivp`. However the solve function still saves the data in the same format using the `celestine.state.Solution` class.

take_timestep(*state*: [State](#))

advance enthalpy, salt, gas and pressure to the next timestep.

Note as of 2023-05-17 removed ability to have adaptive timestepping for simplicity.

Parameters

state (`celestine.solvers.template.State`) – object containing current time, enthalpy, salt, gas, pressure and surface temperature.

Returns

state of system (new enthalpy, salt, gas and pressure) after one timestep.
