1 Non-Dimensional Equations

There are two models (non-dimensional systems of conservation equations to be solved). We work in non-dimensional variables in 1D (z, t). For non-dimensionalisation see Page 6. We use the lagrangian derivative in a moving frame with velocity V .

$$\frac{Df}{Dt} = \frac{\partial f}{\partial t} + V \frac{\partial f}{\partial z}. \quad (1.1)$$

The three primary non-dimensional variables bulk enthalpy (\mathcal{H}_l), bulk salinity (Θ) and bulk gas (Γ) are governed by conservation equations. All other variables are obtained by an equilibrium enthalpy method calculation. The liquid Darcy velocity (W_l) is obtained in the full model by conservation of mass (elliptic pressure equation). In the reduced model it is free to be imposed as a forcing from a brine convection model. In both models gas Darcy velocity is calculated as

$$W_g = \phi_g V_g = \phi_g \left(\mathcal{B} \phi_l^{2q} \frac{\lambda^2}{K(\lambda)} + 2G(\lambda) \frac{W_l}{\phi_l} \right), \quad (1.2)$$

where λ is the ratio of bubble size to tube size. If we assume a scaling for tube size of the form $R_T = R_0 \phi_l^q$, then $\lambda = R_B / R_0 \phi_l^q$. $K(\lambda)$ and $G(\lambda)$ are empirical functions for a spherical centered bubble in Stokes flow in a cylinder.

1.1 Full model

We retain the conservation of total volume ($\phi_s + \phi_l + \phi_g = 1$). This implies changing gas fraction drives liquid flow. Full model conservation equations

$$\frac{D\mathcal{H}}{Dt} = -\frac{\partial}{\partial z} [\mathcal{H}_l W_l] + \frac{\partial^2 \theta}{\partial z^2}, \quad (1.3)$$

$$\frac{D\Theta}{Dt} = -\frac{\partial}{\partial z} [W_l (\Theta_l + \mathcal{C})] + \frac{1}{Le_S} \frac{\partial}{\partial z} \left[\phi_l \frac{\partial \Theta_l}{\partial z} \right], \quad (1.4)$$

$$\frac{D\Gamma}{Dt} = -\frac{\partial}{\partial z} [W_l \chi \omega] - \frac{\partial W_g}{\partial z} + \frac{\chi}{Le_\xi} \frac{\partial}{\partial z} \left[\phi_l \frac{\partial \omega}{\partial z} \right], \quad (1.5)$$

$$\frac{D\phi_g}{Dt} = \frac{\partial}{\partial z} \left[-\Pi(\phi_l) \frac{\partial p}{\partial z} \right]. \quad (1.6)$$

Note: $W_l = -\Pi \frac{\partial p}{\partial z}$.

1.2 Reduced model

We neglect the gas fraction so that $\phi_s + \phi_l = 1$. The conservation equations remain the same Eqs. (1.3) to (1.5). We no longer need to solve for pressure as no flow is driven. The calculation of the enthalpy method is significantly easier as gas fraction is decoupled from thermal solve. We can reconstruct approximations to the full phase fractions ϕ^* as follows. In solid region assume $\phi_l^* = \phi_l = 0$, $\phi_g^* = \phi_g$ and $\phi_s^* = 1 - \phi_g$. In other regions $\phi_s^* = \phi_s$, $\phi_g^* = \phi_g$ and $\phi_l^* = 1 - \phi_s - \phi_g$. This means we must impose the extra constraint that prevents more gas accumulating in a region that would already be saturated. This is done in the numerics by setting $V_g = 0$ if the cell above is such that $\phi_g \geq 1 - \phi_s$.

2 Enthalpy method

From the primary variables ($\mathcal{H}, \Theta, \Gamma$) we seek to reconstruct the other state variables: temperature (θ), liquid salinity (Θ_l), solid salinity (Θ_s), solid fraction (ϕ_s), liquid fraction (ϕ_l), gas fraction (ϕ_g), and dissolved gas concentration (ω).

This is done using the following phase plane information in each region:

- liquid ($\mathcal{H} > \mathcal{H}_L$): $\phi_s = 0$ and solid salinity undetermined so set $\Theta_s = -\mathcal{C}$.
- mush ($\mathcal{H}_E < \mathcal{H} \leq \mathcal{H}_L$): liquidus $\theta = \theta_L(\Theta_l) = -\Theta_l$, and fresh ice $\Theta_s = -\mathcal{C}$.
- eutectic ($\mathcal{H}_S < \mathcal{H} \leq \mathcal{H}_E$): $\theta = -1$, $\Theta_l = 1$.
- solid ($\mathcal{H} \leq \mathcal{H}_S$): $\phi_l = 0$, liquid salinity undetermined so set $\Theta_l = 1$.

The phase boundaries are determined for each region by applying the conditions in both. The gas saturation state depends on $\Gamma_{\text{sat}} = \chi \phi_l$.

- Super saturated ($\Gamma \geq \Gamma_{\text{sat}}$): saturation $\omega = 1$ and $\phi_g = \Gamma - \Gamma_{\text{sat}}$.
- Sub saturated ($\Gamma < \Gamma_{\text{sat}}$): $\phi_g = 0$ and $\omega = \Gamma/\Gamma_{\text{sat}}$.

2.1 Full enthalpy method

For the full enthalpy method calculation we use the relations:

$$\phi_s + \phi_l + \phi_g = 1, \quad (2.1)$$

$$\mathcal{H} = \theta(1 - \phi_g) - \phi_s \text{St}, \quad (2.2)$$

enthalpy in each phase is $\mathcal{H}_l = \theta$, $\mathcal{H}_s = \theta - \text{St}$ and $\mathcal{H}_g = 0$

$$\Theta = \phi_s \Theta_s + \phi_l \Theta_l - \phi_g \mathcal{C}, \quad (2.3)$$

$$\Gamma = \chi \omega \phi_l + \phi_g. \quad (2.4)$$

This is tricky as everything is fully coupled and the enthalpy phase boundaries depend on both salinity and gas content. See Page 15 for derivation.

2.2 Reduced enthalpy method

assuming $\phi_s + \phi_l = 1$ for the enthalpy and salt is extremely useful as it reduces to usual enthalpy method [1]:

$$\phi_s + \phi_l = 1, \quad (2.5)$$

$$\mathcal{H} = \theta - \phi_s \text{St}, \quad (2.6)$$

$$\Theta = \phi_s \Theta_s + \phi_l \Theta_l. \quad (2.7)$$

The gas variables can then be solved independent of phase later using only Γ and $\phi_l(\mathcal{H}, \Theta)$. This yields the following expressions.

$$\mathcal{H}_L = -\Theta, \quad (2.8)$$

$$\mathcal{H}_E = \frac{\text{St}}{1 + \mathcal{C}}(\Theta - 1) - 1, \quad (2.9)$$

$$\mathcal{H}_S = -1 - \text{St}. \quad (2.10)$$

2.2.1 liquid

$$\phi_s = 0,$$

$$\phi_l = 1,$$

$$\theta = \mathcal{H},$$

$$\Theta_l = \Theta,$$

$$\Theta_s = -\mathcal{C}.$$

2.2.2 mush

$$\phi_l = 1 - \phi_s,$$

$$\Theta_s = -\mathcal{C},$$

$$\Theta_l = -\theta,$$

$$\theta = \mathcal{H} + \phi_s \text{St},$$

$$\phi_s = \frac{-B - \sqrt{B^2 - 4AC}}{2A},$$

where $A = \text{St}$, $B = \mathcal{H} - \text{St} - \mathcal{C}$, $C = -(\mathcal{H} + \Theta)$.

2.2.3 eutectic

$$\theta = -1,$$

$$\Theta_l = 1,$$

$$\phi_l = 1 - \phi_s,$$

$$\phi_s = \frac{-(1 + \mathcal{H})}{\text{St}},$$

$$\Theta_s = \frac{\Theta + \phi_s - 1}{\phi_s}.$$

Note that this means that on the mush side of the eutectic we get the solid fraction $\phi_s = (1 - \Theta)/(1 + \mathcal{C})$.

2.2.4 solid

$$\phi_l = 0,$$

$$\phi_s = 1,$$

$$\Theta_l = 1,$$

$$\Theta_s = \Theta,$$

$$\theta = \mathcal{H} + \text{St}.$$

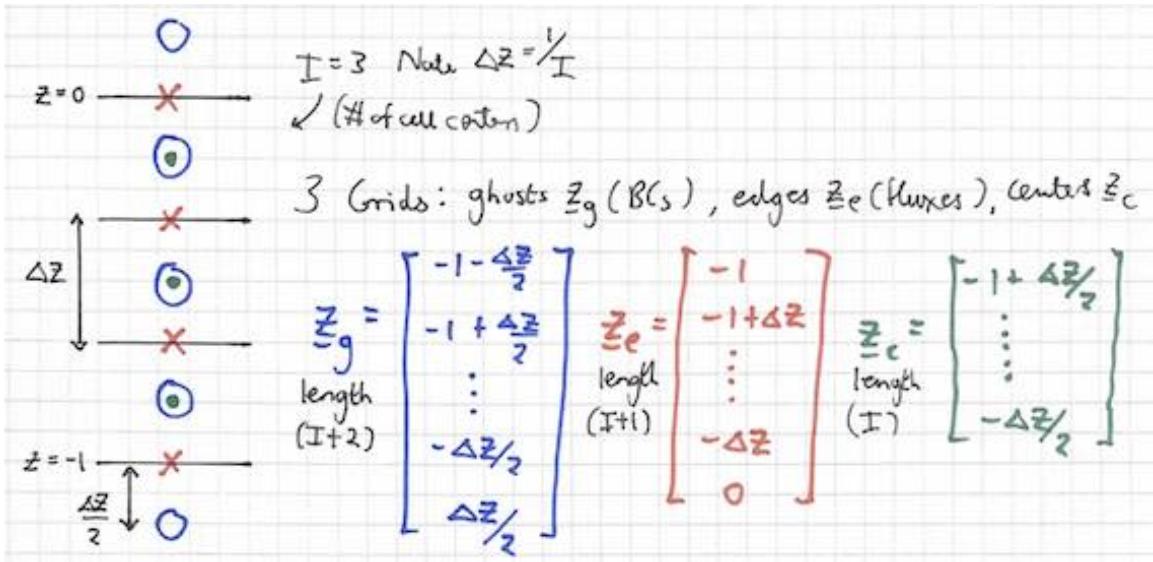

Figure 1: Diagram of three different girds quantities can sit on in spatial discretisation.

3 Spatial discretisation

We discretise the vertical spatial dimension into I cells of width $\Delta z = 1/I$. Each of these cells has a center and two edges. The cell centers lie on the centered grid z_c . The cell edges lie on the edge grid z_e . The cell centers plus a ghost cell for boundary conditions at the top and bottom lie on the ghost grid z_g . See Fig. 1 for a diagram of the grids.

Quantities that lie on the ghost grid are written $\hat{f} = f(z_g, t)$. Quantities that lie on the edge grid are written $\bar{f} = f(z_e, t)$. Quantities that lie on the center grid are written $f = f(z_c, t)$. Note that any quantities on the ghost grid must be given appropriate boundary conditions.

To take derivatives of a quantity on the ghost grid we multiply by the difference matrix D_g . This has dimensions $(I+1, I+2)$ and returns the derivative on the edge grid. To take derivatives of a quantity on the edge grid we multiply by the difference matrix D_e . This has dimensions $(I, I+1)$ and returns the derivative on the center grid. Both of these matrices are all zero apart from $-1/\Delta z$ on the leading diagonal (i, i) , and $1/\Delta z$ on the first off diagonal $(i, i+1)$. Note that matrix multiplication is written \cdot and two quantities on the same grid may be multiplied elementwise.

We introduce two functions for taking ghost grid quantities to edge grid quantities. First the upwinding function \mathcal{U} (ghost, edge). This takes a quantity on the ghost grid and a flux on the edge grid and returns their product, where the ghost value is chosen to be the cell on the side of the edge where the velocity is coming from. Second the geometric mean function \mathcal{G} (ghost). This interpolates a quantity on the ghost grid to the edge grid by taking the geometric average of the two neighbouring cell centers. This is useful as if one of the two cells has no liquid then the edge will have none which makes it impermeable.

We write the spatially discretised equations as

$$\frac{\partial H}{\partial t} = -D_e \cdot \bar{F}_{\mathcal{H}}, \quad (3.1)$$

$$\frac{\partial \Theta}{\partial t} = -D_e \cdot \bar{F}_{\Theta}, \quad (3.2)$$

$$\frac{\partial \Gamma}{\partial t} = -D_e \cdot \bar{F}_{\Gamma}, \quad (3.3)$$

where the fluxes are given by

$$\bar{F}_{\mathcal{H}} = \mathcal{U}(\hat{\mathcal{H}}, \bar{V}) + \mathcal{U}(\hat{\mathcal{H}}_l, \bar{W}_l) - D_g \cdot \hat{\theta}, \quad (3.4)$$

$$\bar{F}_{\Theta} = \mathcal{U}(\hat{\Theta}, \bar{V}) + \mathcal{U}(\hat{\Theta}_l + \mathcal{C}, \bar{W}_l) - \frac{1}{Le_S} \mathcal{G}(\hat{\phi}_l) D_g \cdot \hat{\Theta}_l, \quad (3.5)$$

$$\bar{F}_{\Gamma} = \mathcal{U}(\hat{\Gamma}, \bar{V}) + \mathcal{U}(\chi \hat{\omega}, \bar{W}_l) + \mathcal{U}(\hat{\phi}_g, \bar{V}_g) - \frac{\chi}{Le_{\xi}} \mathcal{G}(\hat{\phi}_l) D_g \cdot \hat{\omega}. \quad (3.6)$$

These fluxes give the finite volume first order upwind scheme in space.

The pressure (if used) is given by solving the following linear system

$$\mathbf{M} \cdot \hat{\mathbf{p}} = \frac{\partial \hat{\phi}_g}{\partial t} + \mathbf{D}_e \cdot \mathcal{U}(\hat{\phi}_g, \bar{V}), \quad (3.7)$$

where the matrix is given by $\mathbf{M} = \mathbf{D}_e \cdot \mathbf{K} \cdot \mathbf{D}_g$. Where \mathbf{K} is the diagonal matrix of size $(I+1, I+1)$ formed by $-\bar{\Pi}$. To prevent the system becoming singular it is necessary to add a small numerical regularisation to this matrix. This prevents the permeability ever being actually zero. Boundary conditions are added to the matrix \mathbf{M} and forcing term to give $W_l = 0$ at $z = 0$ and $p = 0$ at $z = -1$.

4 Solvers

4.1 lagged solver for full model

This solver, chosen as "LU", solves the full model. You specify a constant timestep. The pressure equation Eq. (3.7) requires information about the gas fraction at the current and future timestep. Therefore we take a forward euler timestep of the conservation equations e.g:

$$\mathcal{H}^{n+1} = \mathcal{H}^n - \Delta t \mathbf{D}_e \cdot \bar{\mathbf{F}}_{\mathcal{H}}^n. \quad (4.1)$$

This step gives a value of the gas fraction at both the current and next timestep which is then used to solve for W_l . In this way the liquid velocity is always lagged one timestep behind the other quantities.

4.2 Reduced solver forward euler

This solver, chosen as "RED", solves the reduced model using forward euler for a fixed timestep. It is exactly the same as the lagged solver (see Section 4.1), but without the extra complication of solving for the liquid velocity and the enthalpy method is much simpler.

4.3 Scipy solver

This solver, chosen as "SCI", solves the reduced model using the same finite volume upwind scheme. However, the temporal discretisation is handled entirely by the scipy function solve_ivp in the integration module. This comes with a number of benefits as it handles adaptive timestepping well so long as we specify the max timestep should be small enough to satisfy the stability of explicit treatment of the thermal diffusion term i.e. $\Delta t < \Delta z^2/2$.

Conservation of Water

Liquid phase contains: H_2O , Salt(aq), Gas(aq)

$$\text{mass ratio } S_c = \frac{\text{kg of salt}}{\text{kg of liquid}} \quad \text{density of liquid phase } \rho_c$$

$$\begin{matrix} \text{mass : } W_c + S_c + G_c = 1 \\ \text{ratios } \uparrow \quad \uparrow \quad \uparrow \\ \text{water} \quad \text{salt} \quad \text{gas} \end{matrix} \quad (\text{in principle a function of composition})$$

By analogy solid phase contains: $H_2O(s)$, Salt(s)

$$W_s + S_s = 1$$

$$\frac{\text{kg ice}}{\text{kg of solid}} \downarrow \quad \frac{\text{kg of salt}}{\text{kg of solid}}$$

$$\text{Total mass of } H_2O \text{ in system per volume} = \rho_c W_c + \rho_s s W_s$$

Can be advected in liquid phase

liq Darcy rel

$$\Rightarrow \frac{\partial}{\partial t} (\rho_c W_c + \rho_s s W_s) + \nabla \cdot (\rho_c \underline{u}_c) = 0$$

Assumptions:

$$\star W_c \approx 1, W_s \approx 1$$

$$\star \rho_c = \rho_s = \rho = \text{constant}$$

$$\frac{\partial \phi_g}{\partial t} = \nabla \cdot \underline{u}_c$$

Assume gas volume change
doesn't drive much flow
(i.e. $\phi_g \ll 1$)

$$\Rightarrow \nabla \cdot \underline{u}_c = 0$$

Conservation of Heat

2023/05/11

Enthalpy per unit volume H

$$H_s = \rho_s c_{p,s} (T - T_i) - \rho_s L$$

$$H_e = \rho_e c_{p,e} (T - T_i)$$

T_i is reference temperature

latent heat of fusion
at $T = T_i$: $\frac{H_s}{\rho_s} - \frac{H_e}{\rho_e} = -L$

specific heat capacity

$$C_p \text{ s.t. } \left. \frac{\partial H}{\partial T} \right|_{\text{fixed pressure}} = \varphi C_p.$$

* Neglect enthalpy in gas phase as $\rho_g \ll \rho_s, \rho_e$

$$\Rightarrow \text{total enthalpy per unit vol} = H = \varphi_s H_s + \varphi_e H_e = (\rho_s \varphi_s c_{p,s} + \rho_e \varphi_e c_{p,e})(T - T_i) - \rho_s \varphi_s L.$$

(+ H_0) set enthalpy of liquid at $T = T_i$ to $H_0 = 0$.

Enthalpy can be advected in liquid or conducted:

$$\frac{\partial H}{\partial t} + \nabla \cdot (H_e \mathbf{u}_e) = \nabla \cdot (\bar{k} \nabla T)$$

can use $\frac{\partial \bar{k}}{\partial t} = \nabla \cdot \mathbf{u}_e$

$$\begin{aligned} & \varphi_c C_{p,g} = k_g = 0, \quad C_{p,s} = C_{p,e} = C_p \\ & \Rightarrow \rho_s = \rho_e = \rho \end{aligned}$$

$$\rho C_p (1 - d_g) \frac{\partial T}{\partial t} + \rho C_p \mathbf{u}_e \cdot \nabla T = \rho L \frac{\partial \varphi_s}{\partial t} + \nabla \cdot (k \nabla T)$$

thermal conductivity: $\bar{k} = \varphi_s k_s + d_g k_g + (1 - d_g) k_g$
(typically $k_g \ll k_s, k_g$).

{ can allow insulating effect of air even if we approximate $\varphi_s + d_g \approx 1$ everywhere else as $k_g = 0$

$$\frac{\partial H}{\partial t} + \nabla \cdot (H_e \mathbf{u}_e) = \nabla \cdot (k(1 - d_g) \nabla T)$$

Assume: $C_{p,s} = C_{p,e} = C_p \quad k = \frac{k}{\rho C_p}$

$$\rho_s = \rho_e = \rho$$

$$k_s = k_e = K$$

$$\varphi_s + d_g = 1 \quad (i.e. d_g \ll 1)$$

$$\rho C_p \frac{\partial T}{\partial t} + \rho C_p \mathbf{u}_e \cdot \nabla T = \rho L \frac{\partial \varphi_s}{\partial t} + K \nabla^2 T$$

Conservation of Salt

2023/05/11

$$\frac{\partial}{\partial t} (\rho_e \phi_e S_e + \rho_s \phi_s S_s) + \nabla \cdot (\rho_e S_e \underline{u}_e) = \nabla \cdot (\rho_e \phi_e D_s \nabla S_e)$$

Enthalpy $H \sim \rho C_p \Delta T$

(from temp scale)

$$\Rightarrow \underline{H}_i = \frac{H_i}{\rho C_p \Delta T} = \theta \quad H_s = \frac{H_s}{\rho C_p \Delta T} = \Omega - \frac{L}{\rho C_p}$$

Stefan number.

$$\text{Bulk enthalpy: } H = \frac{H}{\rho C_p \Delta T} = \phi_s H_s + \phi_e H_e = \phi_s (\Omega - \theta) + \phi_e \Omega = (1 - \phi_g) \Omega - \phi_s \theta$$

$$\text{Bulk salt: } \Theta = \frac{S - S_i}{\Delta S} = \phi_s \frac{(S_s - S_i)}{\Delta S} + \phi_e \frac{(S_e - S_i)}{\Delta S} - \phi_g S_i = \phi_s \Theta_s + \phi_e \Theta_e - \phi_g C_e$$

$$\text{Bulk gas: } \Gamma = \frac{G}{P_g} = \left(P_c \frac{f_{sat}}{P_g} \right) w_i + \phi_g = \chi w \phi_e + \phi_g$$

neglect $\phi_g \ll 1$ for reduced

1D Non Dimensional Equations

2023/05/13

$$\frac{D\phi_g}{Dt} = \frac{\partial w_e}{\partial z}$$

$$\lambda = \frac{R_B}{R_T} = \frac{R_B}{R_0 \phi_e^2} = \frac{1}{\phi_e^2}$$

$$w_g = \phi_g \left(\frac{\gamma_B}{k_e(\lambda)} + \frac{2G(\lambda)}{\phi_e} w_e \right)$$

$$\left(\frac{D\mu}{Dt} + \frac{\partial}{\partial z} (\mu_e w_e) \right) = \frac{\partial^2 \theta}{\partial z^2} \quad \begin{matrix} k_s = k_e = k_g \\ \text{if } \frac{k_s}{k_g} = 0 \text{ then } \frac{\partial}{\partial z} ((1-\phi_g) \frac{\partial \alpha}{\partial z}) \end{matrix}$$

$$\mu = (1-\phi_g)\alpha - \phi_s S_t \quad \mu_s = \alpha$$

$$\left(\frac{D\theta}{Dt} + \frac{\partial}{\partial z} ((\theta_e + \alpha_e) w_e) \right) = \frac{1}{L_{es}} \frac{\partial}{\partial z} \left(\phi_e \frac{\partial \theta_e}{\partial z} \right)$$

$$\theta_s = \phi_s \theta_s + \phi_e \theta_e - \phi_g \alpha$$

$$\left(\frac{D\Gamma}{Dt} + \frac{\partial}{\partial z} (\chi_w w_e) + \frac{\partial w_g}{\partial z} \right) = \frac{\chi}{L_{eg}} \frac{\partial}{\partial z} \left(\phi_e \frac{\partial w}{\partial z} \right)$$

$$\Gamma = \chi_w \phi_e + \phi_g$$

$$\text{Linear liquidus } T_L(S_e) = T_i + \Gamma'_L(S_i - S)$$

$$\therefore \Delta T = \Gamma'_L \Delta S$$

$$\Rightarrow \Theta_L(\Theta_e) = -\Theta_e$$

Solidus (no segregation coeff)

$$\Theta_S = -1$$

Non-Dimensional Numbers

2023/05/13

$$St = \frac{L}{C_p \Delta T}$$

$$Gr = \frac{S_i}{\Delta S}$$

$$Le_s = \frac{D_s}{H}$$

$$Le_j = \frac{D_j}{H}$$

$$\chi = \frac{P_e f_{sat}}{\rho g}$$

$$B = \frac{V_{st}}{V} = \frac{\rho_e g R_o^2 L}{3 \mu k}$$

$$\lambda = \frac{R_o}{R_o}$$

We also have non-dimensional BCs:

$Z=0$ (top):

Cold temp: $\Theta_0(t)$

No salt flux or fixed salinity Θ_0

Fixed gas e.g. $f_0 = f_{sat}(H_0, \Theta_0)$

$Z=-1$ (ocean):

$\Theta(Z=-1) = \Theta_0$

Ocean salinity $\Theta(Z=-1) = 0$

$f(Z=-1) = \chi$

Reduced Model

(makes enthalpy method much more tractable).

2023/05/13

* When gas doesn't move $\dot{\phi}_g$ is controlled by freezing, for saturated liquid

X is the maximum volume of gas that can be enclosed

Approximation $X \ll 1 \Rightarrow$ neglect terms of $O(\dot{\phi}_g)$ except in gas equation

$$H = Q - \dot{\phi}_S St \quad \text{and} \quad \dot{\phi}_S + \dot{\phi}_L = 1.$$

other conservation eqns
stay the same.

$$\Theta = \dot{\phi}_S \Theta_S + \dot{\phi}_L \Theta_L \quad \therefore \frac{\partial W_L}{\partial Z} \approx 0 \quad (\text{no flow driven by gas})$$

$$r^* = X \dot{\phi}_L w + \dot{\phi}_g$$

* This can breakdown if large gas volume accumulates below impermeable layer or gas velocity becomes much larger than liquid velocity.

* For consistency impose extra condition that $\dot{\phi}_g$ is no longer than void fraction

Approximate scheme: (No gas front)

In reality

$$\text{Solid} : \dot{\phi}_S = 1 \quad \dot{\phi}_L = 0$$

$$\dot{\phi}_S = 1 - \dot{\phi}_g, \dot{\phi}_L = 0 \quad (\text{the same})$$

$$\text{other phases (mush/liquid)} : \dot{\phi}_S + \dot{\phi}_L = 1$$

$$\dot{\phi}_S \text{ the same}$$

$$\dot{\phi}_L = 1 - \dot{\phi}_S - \dot{\phi}_g$$

$$\therefore \left\{ \begin{array}{l} \dot{\phi}_g \leq \text{void frac} = 1 - \dot{\phi}_S \\ \text{so that } \dot{\phi}_L \geq 0 \end{array} \right.$$

This stops

arbitrary gas accumulating in one cell and gives Bouyancy Layer.

* This approach lets us calculate r^* given H, Θ, W_L as input.

6 Full enthalpy method derivation

Enthalpy Method With $\phi_s + \phi_l + \phi_g = 1$.

Bulk temperature T , Salinity S

$$S = \phi_s S_s + \phi_l S_e \text{ as } S_g = 0.$$

Linearised phase boundaries

d_c distribution coeff

in mushy phase approximate $S_g = d_c S_e$.

$$T_L(S) = T_E - \Gamma(S_E - S) \quad (1)$$

$$T_S(S) = \max(T_E, T_E - \frac{\Gamma}{d_c}(S_E - d_c S)) \quad (2)$$

eutectic point (T_E, S_E) s.t $T_L(S_E) = T_S(S_E) = T_E$

fresh water freezes at 0°C $T_L(0) = 0 \Rightarrow T_E + \Gamma S_E = 0$

ϕ_g reduces maximum bulk salinity by occupying volume

* Phase space for sub-eutectic mushy layer changes w/ ϕ_g

consider liquid phase $S = \phi_l S_e \quad 0 \leq S \leq S_E$ for sub-eutectic mushy layer.

$\phi_l = 1 - \phi_g$ as $\phi_s = 0 \Rightarrow S = (1 - \phi_g) S_E$

$\therefore 0 \leq S \leq (1 - \phi_g) S_E$ so as ϕ_g increases eutectic point

shifts inwards (on liquidus $\phi_g = 0, S = (1 - \phi_g) S_E$ } sub into solidus $\phi_g = 0, S = (1 - \phi_g) S_E$ } (1) & (2))

$$0 \leq S \leq S_{\max} = (1 - \phi_g) S_E$$

Define Bulk Quantities

(β_{sat} : constant otherwise
going to get non linear equations
for ϕ_g anyway).

$$\text{Enthalpy: } H = \phi_S H_S + \phi_L H_L + \phi_g H_g$$

$$\text{Salt: } S = \phi_S S_S + \phi_L S_L$$

$$\text{Gas: } G = \rho_i \beta_i \phi_i + \rho_g \phi_g \quad G = \rho_g P$$

$$\text{take } \rho_i = \rho_s = \rho = \text{const} \quad \varepsilon = \rho_g / \rho \ll 1.$$

$$\rho_g = \text{const}$$

Neglect H_g term as $O(\varepsilon)$.

$$\text{Take } (\rho_i)_i = (\rho_s)_s$$

$$H_S = \rho C_p (T - T_i) - \rho L$$

$$H_L = \rho C_p (T - T_i)$$

$$H_g = 0.$$

$$H = \rho C_p (T - T_i) (\phi_S + \phi_L) - \phi_S \rho L \quad \leftarrow$$

Note only freezing/melting changes latent heat term
gas acts as a void carrying no enthalpy

$$\text{so have effective heat capacity } H = \rho C_{\text{eff}} (T - T_i) - \rho \phi L$$

Breaks down when $\phi_g = 1$ ($C_{\text{eff}} = C_p(1 - \phi_g)$).

as no energy can be retained in system.

ND.

$$H = \rho c p \Delta T H \quad Q = \frac{T - T_i}{\Delta T} \quad \Delta T = T_f - T_i \\ \Theta = \frac{S - S_i}{\Delta S} \quad \Theta_i = \frac{S_i - S_i}{\Delta S}, \quad \Theta_s = \frac{S_f - S_i}{\Delta S}$$

$$\theta_s = \max\left(-1, -\frac{1}{d_c}\left(\theta + \frac{r\epsilon}{1-d_c} + \epsilon\right)\right).$$

$$\therefore u_s^+(t) = (1-r) \max\left(-1 - st, -\frac{1}{d_c}\left(\theta + \frac{r\epsilon}{1-d_c} + \epsilon\right) - st\right).$$

Solid Region \oplus : $\phi_i = 0, \theta, MA, w = 1$

$$y = \theta(1-f_g) - (1-f_g)st = (1-f_g)(\theta - st)$$

$$G = \phi_s \theta_s - \frac{f_g \epsilon}{1-d_c} = (1-r)\theta_s - \frac{r\epsilon}{1-d_c}$$

$$r = f_g$$

$$\theta_S = \underline{\theta} + \frac{r_{ce}}{1-d_c}$$

$$\theta = \frac{u}{1-n} + S$$

$$f_g = n$$

$$f_S = 1 - n$$

Calculating Phase Boundaries.

Need total phase boundaries

$$H_{L,E,S}(\theta, \Gamma) \text{ & } \Gamma_{\text{sat}}(H, \theta).$$

Note that for $\Gamma \leq \Gamma_{\text{sat}}$ phase boundaries are independent of Γ

$$\therefore \Gamma_{\text{sat}}(H, \theta) = \chi \tilde{\phi}_e(H, \theta).$$

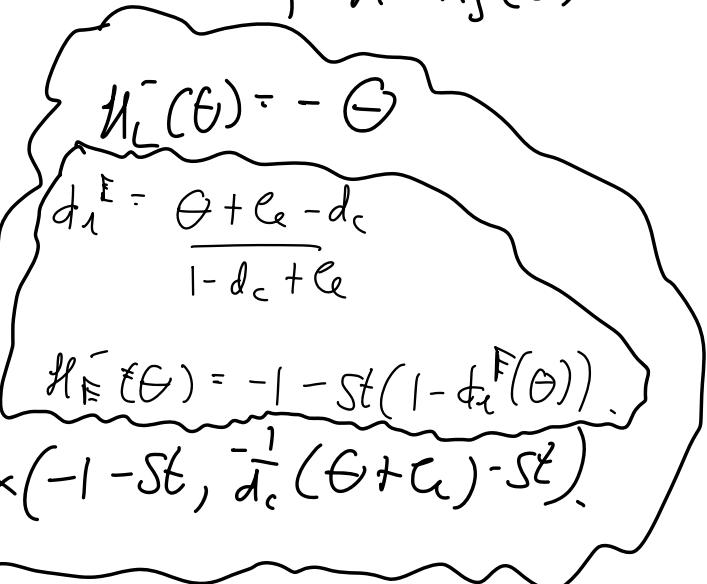

where $\tilde{\phi}_e = \phi_e$ subsaturated

$$\Gamma_{\text{sat}}(H, \theta) = \begin{cases} \infty & H \geq H_L^-(\theta) \\ \chi \left(1 - \left(\frac{\theta - H}{ST} \right) \right), & H_E^-(\theta) \leq H < H_L^-(\theta) \\ \chi \left(1 + \left(\frac{H + 1}{ST} \right) \right), & H_S^- \leq H \leq H_E^-(\theta) \\ 0 & H \leq H_S^-(\theta) \end{cases}$$

$$A = 1 - d_c$$

$$B = (1 - d_c)H + C_e + ST$$

$$C = C_e H - ST \theta$$

To calculate

phase boundaries we need intersects with Γ_{sat}

occurs at $\Gamma_L^{\text{sat}} = \Gamma_{\text{sat}}(\mathcal{H}_L^-(\theta), \theta)$

$$\Gamma_E^{\text{sat}} = \Gamma_{\text{sat}}(\mathcal{H}_E^-(\epsilon), \epsilon)$$

$$\Gamma_S^{\text{sat}} = \Gamma_{\text{sat}}(\mathcal{H}_S^-(\theta), \theta)$$

then $\mathcal{H}_L(\theta, r) = \begin{cases} \mathcal{H}_L^-(\epsilon) & , r \leq \Gamma_L^{\text{sat}}(\theta) \\ \mathcal{H}_L^+(\theta, r) & , r > \Gamma_L^{\text{sat}}(\theta) \end{cases}$

same for $E \neq S$.

when $\mathcal{H} = \mathcal{H}_L^-(\epsilon)$ $\Gamma_L^{\text{sat}} : \infty$

when $\mathcal{H} = \mathcal{H}_S^-(\theta)$ $\Gamma_S^{\text{sat}} : 0$

$\mathcal{H} = \mathcal{H}_E^-(\epsilon)$ $\Gamma_E^{\text{sat}} = \chi \left(\frac{\theta + \epsilon - d_c}{1 - d_c + \epsilon} \right)$

$$\mathcal{H}_E^- = 1 - \text{SE}(1 - \phi_1^E(\theta))$$

$$\Gamma_E^{\text{sat}} = \chi \left(1 - (1 - \phi_1^E(\theta)) \right)$$

$$= \chi \phi_1^E(\theta) = \chi \left(\frac{\theta + \epsilon - d_c}{1 - d_c + \epsilon} \right)$$

$$H_L(\theta, r) = \begin{cases} -\theta, & r \leq \chi \\ -\left(\theta + \frac{c_e}{1-d_c} \left[\frac{r-\chi}{1-\chi} \right] \right), & r > \chi \end{cases}$$

$$H_E(\theta, r) = \begin{cases} -1 - St(1 - \phi_i^E(\theta)), & r \leq \chi \phi_i^E(\theta) \\ -1(1 - \phi_g) - \phi_S St, & r > \chi \phi_i^E(\theta) \end{cases}$$

$\phi_i^E = \frac{\theta + c_e}{1 + c_e}$ same as before
 $(d_c = 0)$

$$\phi_g = r - \frac{\chi(\theta + c_e)}{1 + c_e}$$

$$\phi_S = 1 - \phi_i^E - \phi_g$$

$$H_S(\theta, r) = \begin{cases} \max(-1 - St, -\frac{1}{d_c}(\theta + c_e) - St), & r = 0 \\ (1 - r) \max(-1 - St, -\frac{1}{d_c} \left(\frac{\theta + \frac{r c_e}{1 - d_c} + c_e}{1 - r} - St \right)), & r > 0 \end{cases}$$

Bands: H can be anything.
 $0 \leq r \leq 1$.

$$-\frac{c_e}{(1-d_c)} \leq \theta \leq \theta_{\max} = 1 - \phi_g \left(1 + \frac{c_e}{1-d_c} \right)$$

bulk fresh

(the reduced eutectic point)
for a given ϕ_g $\theta_{\max}(\phi_g)$
s.t $\theta_{\max}(0) = 1$.

To plus $\Theta_{max}(r)$

we can we defined in liquid $f_g = \frac{r-\chi}{1-\chi}$.

$$r \geq \chi \quad f_g$$

$$r < \chi \quad f_g = 0$$

$$\Theta_{max} = \begin{cases} 1, & r \leq \chi \\ 1 - \left(\frac{r-\chi}{1-\chi} \right) \left(1 + \frac{c}{1-d_c} \right), & r > \chi. \end{cases}$$
